Subject:  881 Alma Real Drive  
Pacific Palisades, CA  
Seismic Screening Report  
JLA Job no. 13110-20

Dear Mr. Ceragioli,

Per your request, we have performed a seismic screening of the building located at 881 Alma Real Drive in Pacific Palisades, California. Our services included a site visit performed to observe the existing conditions of the exposed structural systems, review of the available record drawings, and an evaluation of the existing structural systems of the building.

Building Description

The building is located at 881 Alma Real, at the corner of Alma Real Drive and La Cruz Drive, in Pacific Palisades, California. The building consists of a three-story wood framed structure above grade over a 3-story subterranean concrete framed structure with a rectangular plan measuring approximately 181 feet by 158 feet. The building was constructed in 1981 and underwent a voluntary seismic strengthening in 1999.

As part of a previous project, JLA observed this building in December 2010 and took notes based on additional documentation available at that time:

- December 15, 1999 version of the Myers Houghton & Partners seismic strengthening drawings (S-1 through S-12)
- January 19, 2007 WRA Engineering Seismic Assessment Report
Construction

Roof & Floor Construction:
The gravity framing at the 2nd floor through the roof consists of open-web joists framing to steel beams which are supported by steel columns. At the first floor podium as well as the parking levels below grade, the gravity system consists of a concrete slab spanning to precast concrete T-beams which span to precast concrete girders supported by concrete columns.

Foundation System:
The foundation system probably consists of a concrete slab on grade, with concrete pads supporting the concrete columns and continuous concrete footings supporting the concrete walls.

Lateral-Load-Resisting-System:
The lateral-force-resisting system of the 2nd through roof levels consists of plywood diaphragms that transfer seismic inertial loads to wood shear walls as well as steel concentric braced frames. The forces from above grade are transferred through the concrete diaphragm at the first floor to the perimeter basement concrete shear walls. Steel concentric braced frames as well as additional plywood shear walls were added during the voluntary seismic strengthening of 1999.

Observations

The exposed structural elements appeared to be in fair condition considering the age of the building.

Seismic Evaluation Criteria

General: The property was evaluated based on the University of California Seismic Safety Policy dated August 25, 2011. The seismic policy provides 7 seismic performance ratings: I thru VII. Please refer to Appendix for more info on Seismic Safety Policy & rating.

Seismic Evaluation

• The structure has a complete load path to transfer seismic inertial forces to the foundations.
• There are no significant strength or stiffness discontinuities in the vertical elements of the lateral-load-resisting system.
• The roof & floor diaphragms are continuous with no major openings.
• The voluntary seismic upgrade performed in 1999 enhanced the existing lateral load resisting system. It appears that adequate length of plywood shear walls and braced frames bays have been provided for the size, configuration, and age of the building. A major seismic disturbance is anticipated to result in some structural and/or nonstructural damage that would represent low life hazards.

Seismic Rating

IV

Limitations

This limited seismic screening was based on our limited site observations of the exposed structural members and a review of the plans. Services were performed by JLA in a manner consistent with the level of care and skill ordinarily exercised by members of the profession currently practicing under similar conditions. The structural observations and recommendations represent our opinion and are not intended to preempt the responsibility of the original design consultants in any way. No other warranty, expressed or implied, is made.

If you have any questions, please do not hesitate to call us.

Yours truly,

John Labib & Associates

John Labib, S.E.
President
## APPENDIX A

### Earthquake Performance Levels For Existing Buildings

This series of definitions was developed by the California State University, the University of California, the California Department of General Services, and the Administrative Office of the Courts from 1995 through 2009.

### Table A.1. Determination of Expected Seismic Performance Based on Structural Compliance with the 2010 Edition, California Code of Regulations, Part 2, California Building Code (CBC)

<table>

Notes:

1. Earthquake damageability levels are indicated by Roman numerals I through VII. Assignments are to be made following a professional assessment of the building's expected seismic performance as measured by the referenced technical standard and earthquake ground motions. Equivalent Arabic numerals, fractional values, or plus or minus values are not to be used. These assignments were prepared by a task force of state agency technical personnel, including the California State University, the University of California, the California Department of General Services, the Division of the State Architect, and the Administrative Office of the Courts. The ratings apply to structural and non-structural elements of the building as contained in Chapter 34, CBC requirements. These definitions replace those previously used by these agencies.

2. Chapter 34 of the California Building Code, current edition, regulates existing buildings. It uses and references the American Society of Civil Engineers Standard Seismic Rehabilitation of Existing Buildings, ASCE-41. All earthquake ground motion criteria are specific to the site of the evaluated building. The CBC definitions for earthquake ground motions to be assessed are paraphrased below for convenience:

   BSE-2, the 2,475-year return period earthquake ground motion, or 150% of the Maximum Considered Earthquake ground motion for the site.
   BSE-C, the 975-year return period earthquake ground motion.
   BSE-1, two-thirds of the BSE-2, nominally, the 475-year return period earthquake ground motion.
   BSE-R, the 225-year return period earthquake ground motion.

   Occupancy Category is defined in the CBC Table 1604A.5. The occupancy category sets the level of required seismic building performance under the CBC. Occupancy Category IV includes acute care hospitals, fire, rescue and police stations and emergency vehicle garages, designated emergency shelters, emergency operations centers, and structures containing highly toxic materials where the quantities exceed the maximum allowed quantities, among others. Occupancy categories I-III includes all other building uses that include most state owned buildings.

3. Implied Risk to Life is a subjective measure of the threat of a life threatening injury or death that is expected to occur in an average building in each rank following the indicated technical requirements. The terms negligible through dangerous are not specifically defined, but are linguistic indications of the relative degree of hazard posed to an individual occupant.

4. Implied Damageability is the level of damage expected to the average building in each rank following the indicated technical requirements when a BSE-1 level earthquake occurs. The damage includes both the structural and non-structural systems, but does not consider furnishing and tenant contents. Damage is measured as the ratio of the cost to repair the building divided by the current cost to reconstruct the building from scratch. Such assessments are to be completed to the requirements of ASTM E-2026 at ASTM Level 1 or higher in order to be considered appropriate, where the damage ratio is the Scenario Expected Loss (SEL) in the BSE-1 earthquake ground motion evaluated. ASTM E2026 is the standard for evaluating the seismic damageability of buildings for financial transactions.

5. In those cases where the engineer making the assessment using the requirements for a given Rating Level concludes that the expected seismic performance is consistent with a one-level higher or lower rating, this
alternative Rating Level may be assigned if and only if an independent technical peer reviewer concurs in the evaluation. The peer review must be completed consistent with the requirements of Chapter 34 of the CBC. It is anticipated that most projects that are independently peer reviewed from the initiation of the evaluation and/or design process will qualify for a higher Rating than those buildings, which have not been so reviewed at all. The second column under Peer Review the Ratings have been assigned when this occurs. Note that peer review is unlikely to improve buildings rated as VI or VII because they have fundamental seismic system flaws. The ratings for I and II are not changed because the performance increment between levels is so large.

6. Historically the University of California has used the terms good, fair, poor and very poor to distinguish the relative seismic performance of buildings. The concordance of values in the table above is approximate. The former rating procedures did not provide specific performance levels as is done herein, but were sentence fragments for qualitative performance and are recalled below for historical purposes only:

A Good seismic performance rating would apply to buildings and other structures whose performance during a major seismic disturbance is anticipated to result in some structural and/or nonstructural damage and/or falling hazards that would not significantly jeopardize life. Buildings and other structures with a Good rating would have a level of seismic resistance such that funds need not be spent to improve their seismic resistance to gain greater life safety, and would represent an acceptable level of earthquake safety.

A Fair seismic performance rating would apply to buildings and other structures whose performance during a major seismic disturbance is anticipated to result in structural and nonstructural damage and/or falling hazards that would represent low life hazards. Buildings and other structures with a Fair seismic performance rating would be given a low priority for expenditures to improve their seismic resistance and/or to reduce falling hazards so that the building could be reclassified Good.

A Poor seismic performance rating would apply to buildings and other structures whose performance during a major seismic disturbance is anticipated to result in significant structural and nonstructural damage and/or falling hazards that would represent appreciable life hazards. Such buildings or structures either would be given a high priority for expenditures to improve their seismic resistance and/or to reduce falling hazards so that the building could be reclassified as Good, or would be considered for other abatement programs, such as reduction of occupancy.

A Very Poor seismic performance rating would apply to buildings and other structures whose performance during a major seismic disturbance is anticipated to result in extensive structural and nonstructural damage, potential structural collapse, and/or falling hazards that would represent high life hazards. Such buildings or structures either would be given the highest priority for expenditures to improve their seismic resistance and/or to reduce falling hazards so that the building could be reclassified Good, or would be considered for other abatement programs such as reduction of occupancy.

7. For reference, the historically used Division of the State Architect and Seismic Safety Commission levels corresponds approximately to the new Performance Level numerical values in this table.
